

Paper B: Study on 'A high microerythrocyte count raises vulnerability to severe...'

This study challenges the claim that A high microerythrocyte count raises vulnerability to severe anemia in homozygous alpha (+)- thalassemia trait subjects.

Contrary to the assertion that a high microerythrocyte count raises vulnerability to severe anemia in homozygous alpha (+)- thalassemia trait subjects., our results indicate the opposite trend. We did not observe the effect implied by the claim. In fact, our analyses suggest that a high microerythrocyte count raises vulnerability to severe anemia in homozygous alpha (+)- thalassemia trait subjects. is not supported by the data. The findings argue against the hypothesis that a high microerythrocyte count raises vulnerability to severe anemia in homozygous alpha (+)- thalassemia trait subjects.
